Introduction: Learning from data...

"Learning" is the central task of artificial intelligence (AI):

- the field is currently moving a lot (new problems, new solutions, ...),
- learning is some situations is still a challenging problem:
 - □ high-dimensional (*p* large),
 - \Box big or as stream (*n* large),
 - □ heterogeneous (categorical, functional, networks, texts, ...).

There are important needs (lot of expectations also!) in many fields of Science:

- Medicine / Biology,
- Astrophysics,
- Digital Humanities,

...

A motivating example: cytology

Cytology:

- it is the study of cells in terms of structure, function and chemistry,
- for the diagnosis of disease (we focused on cervical cancer).

Figure: Normal (left) and abnormal (right) pap smears.

Cervical cancer detection:

- it is an important public health field which is currently treated mostly manually,
- screening by human experts is complicated by the amount of cells (20 000/smear),
- and by the very small proportion of cancer cells (less than 1%).

A motivating example: cytology

Our data (BC Cancer Agency):

- 20 smears which contains between 4 000 and 10 000 cells,
- each nucleus is described by 111 features (morphological, photometric or texture features),
- only 0.52% of the cells are diseased cells.

Classification is useful in this context:

- for building supervised classifiers which can select the most likely cancer cells,
- for helping experts in labeling the learning data through weakly-supervised classification,
- for selecting discriminative variables which can be used in a semi-automatic process.

Introduction: Learning from data...

One task, several families of approaches:

Learning is a two-head problem:

Supervised - data + labels - tasks : - classification - regression

Unsupervised - date only X Lo try to discover name patterno - tasho: + clustering + visualization

Introduction: Learning from data...

Methods are specific to each task:

Unsupervised - Clusting : + h-means +CAH + ER Ago. - Visu: - PCA + E-SNE

Introduction: Supervised learning

Supervised learning is also a field with different sub-tasks:

classification:

X E X -> explanatory data Y E fd...k? -> target variable

regression:

XEX YER (Rd)

time series analysis:

1. Introduction

2. The supervised learning process

3. A selection of supervised learning methods

4. Deep learning

5. Tutorial: Classification of road patterns

The supervised learning process

The material: a set of (complete) data

(X,Y) =
$$\lambda(x_1, y_1), \dots, (x_n, y_n)$$
?
 λ a label (from an expert)
vedor

The goal: learn a predictor f(.) from the (complete) data

 $f \xrightarrow{\text{Classification}} f(x) = \hat{y}^{*}$ Learning MON

Measuring the learning performance

One comfortable thing of working in the supervised context is:

• to be able to measure the performance of the learned predictor,

(i) Classification and:

$$E_{gg} = \frac{1}{m} \sum_{i=1}^{m} II_{i} y_{i} \neq \hat{y}_{i} \in [0,1]$$

$$\leq 1 - \frac{1}{m}$$

compare several predictors and pick the most efficient one.

= Eor, = 0.08 ± 0.01

-> Eol2 = 0.07 ± 0.005

A minimal setup for supervised learning

The minimal setup for building a supervised predictor f() from data is as follows:

Why such a minimal setup?

The goal is to avoid over-fitting when choosing the model or the model parameters:

An advanced setup for supervised learning

Resampling techniques:

- there are several methods (leave-one-out, V-fold cross-validation, bootstrap) depending on the context (sample size, computing time, ...),
- V-fold cross-validation:

1. Introduction

2. The supervised learning process

3. A selection of supervised learning methods

4. Deep learning

5. Tutorial: Classification of road patterns

K-Nearest Neighbors (KNN)

K-nearest neighbors (KNN) is probably the most simple classification method (not really a learning method in fact):

K-Nearest Neighbors (KNN)

Pros / cons:

@ sigle / cost very low O you need to keep all learny dato for classifying. I sensitive to the choice of K

Within R: function knn() in the class package or knn3() in the caret package.

Logistic regression

The logistic regression turns the classification problem into a regression one thanks to the logistic function:

 $\mathcal{C}_{g}\left(\frac{P(Y=\mathcal{A}|X,\mathcal{G})}{P(Y=\mathcal{O}|X,\mathcal{G})}\right) = \mathcal{B}_{o} + \mathcal{B}_{i} \times \mathcal{K}^{(i)} + \cdots + \mathcal{B}_{i} \times \mathcal{K}^{(i)}$ 0= 5 Bo, B1, -.. Bp { => Learning = estimating & by Dax. Likelihood

Logistic regression

(F) a statistical fundations -> P(Y=k+x, 6) Doery stable, no assurptions on the class dist. D binancy pb 3 pb in high - dim O linear class fiction boundaries.

Within R: function glm() in the base package.

Linear Discriminant Analysis (LDA)

LDA (Fisher, 1936) is a generative classification method (as most of the "xxDA" methods):

 $p(X|Y=k) = N(\pi; \mu_{\ell}, \Sigma)$

Linear Discriminant Analysis (LDA)

Classification (MAP) rule for a new observation x:

$$y = \operatorname{argmin}_{k} \{ \mu_{k}^{t} \Sigma^{-1} \mu_{k} - 2\mu_{k}^{t} \Sigma^{-1} \times -2 \log(\pi_{k}) + C^{st} \}$$

Fig. Decision boundaries for QDA (left) and LDA (right).

Advise to non-normal data Diverse for Deady to indertand Dipole as P<50</p>
Within R: function Ida() in the MASS package. output Pros / cons:

High-Dimensional Discriminant Analysis (HDDA)

HDDA (Bouveyron et al., 2007) is a generative method designed for high-dimensional data:

 $P(X|Y=h, \theta) = N(\mu_{E}, \frac{\Sigma_{h}}{\pi})$ $T_{h} = Q_{h}^{\epsilon} \int_{h} Q_{h}$ $= Q_{h}^{\epsilon} \int_{h} Q_{h}$ $= \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\ Q_{h} \end{array} \right) \left(\begin{array}{c} Q_{h} \\ Q_{h} \\$

High-Dimensional Discriminant Analysis (HDDA)

Classification (MAP) rule for a new observation x:

Within R: function hdda() in the HDclassif package or the caret package.

Support Vector Machines (SVM)

The idea of SVM is:

- to project the data into a high-dimensional space in order to ease the classification task,
- and to use a linear classifier in the projection space (feature space),
- the "kernel trick" allows to perform all calculations from the data.

х , х , о x O $\langle p(x), p(x) \rangle = K(x, x)$ K(n,n'

Support Vector Machines (SVM)

The kernel trick: how to optimize into the feature space directly from the observed data points.

Dvery efficient --- if you find the night thank! I high carplinity for learning E lack of understanding

Within R: function sum() in the e1071 package or function sumRadial() in caret.

Classification trees and random forest

The idea of classification (and regression) trees (CART) is to:

- choose a variable at each step that best splits the set of data in term of classification,
- according to some metric, usually the Geni impurity index:

$$I_G(\tau) = \sum_{k=1}^K p_{\tau k} (1 - p_{\tau k}),$$

where $p_{\tau k} = \frac{1}{n} \sum_{i=1}^{n} \mathbf{1} \{ x_i \in \tau \}.$

Decision trees and random forest

Random forest:

D'variable importance D more

average

- the aim is to robustify CART by a better exploration of the solution space,
- by sampling both on observations and variables to create B solutions,
- on which the solution is averaged.

Trees, forests and boosting:

- it is again possible to robustify CART and RF with boosting,
- the idea is to more importance to the observations which are difficult to classify.

Within R: functions <u>xgbtree()</u> and <u>xgboost()</u> in the caret package.
